

Recall prime numbers:

Their factors are only 1 and itself

ex: 2, 3, 5, 7, 11, 13, ...

$$2 = 2 \times 1 \text{ only}$$

$$3 = 3 \times 1 \text{ only}$$

$$5 = 5 \times 1 \text{ only}$$

⋮

All whole numbers that are greater than 2 can be written as a **product** of primes. To do this, we use factor trees:

\nwarrow
multiplication

Ex: Prime factor 15

$$\begin{array}{c} 15 \\ / \quad \backslash \\ 3 \times 5 \end{array}$$

\Rightarrow we say, "the prime factorization of 15 is 3×5 "

Ex: Prime factor 3300

$$\begin{array}{ccc} 3300 & \Rightarrow & 3300 = 2 \times 2 \times 3 \times 5 \times 5 \times 1 \\ & & = 2^2 \times 3 \times 5^2 \times 11 \\ & & \begin{array}{c} / \quad \backslash \\ 33 \quad 100 \\ / \quad \backslash \quad / \quad \backslash \\ 3 \quad 11 \quad 10 \quad 10 \\ / \quad \backslash \quad / \quad \backslash \\ 5 \quad 2 \quad 5 \quad 2 \end{array} \end{array}$$

Note: For large numbers you may be able to draw more than one factor tree. This is fine, you will get the same answer.

Greatest Common Factor (GCF)

Greatest Common Factor (GCF)

The largest factor common between 2 or more numbers.

ex: GCF 16 and 32

$$\begin{array}{l} 16: 1, 2, 4, 8, \textcircled{16} \\ 32: 1, 2, 4, 8, \textcircled{16}, 32 \end{array}$$

\hookrightarrow GCF

For large numbers, prime factorization is useful:

Ex: GCF between 138 and 198.

$$\begin{array}{ll} 138 = 2 \cdot 3 \cdot 23 & 198 = 2 \cdot 3^2 \cdot 11 \\ \begin{array}{c} 138 \\ \diagdown \quad \diagup \\ \textcircled{2} \quad 69 \\ \diagdown \quad \diagup \\ \textcircled{3} \quad \textcircled{23} \end{array} & \begin{array}{c} 198 \\ \diagup \quad \diagdown \\ \textcircled{2} \quad 99 \\ \diagup \quad \diagdown \\ \textcircled{3} \quad \textcircled{3} \\ \diagup \quad \diagdown \\ 9 \quad \textcircled{11} \end{array} \end{array}$$

* Take each common factor and multiply them together to get the GCF *

$$\begin{array}{l} 138: \textcircled{2} \cdot \textcircled{3} \cdot 23 \\ 198: \textcircled{2} \cdot \textcircled{3} \cdot 11 \\ \downarrow \quad \downarrow \\ 2 \times 3 = 6 \end{array}$$

∴ The GCF
is 6

Lowest Common Multiple (LCM)

The smallest multiple common across 2 or more numbers.

ex: LCM between 18 and 20?

$$\begin{array}{l} 18: 18, 36, 54, 72, 90, 108, 126, 144, 162, \textcircled{180} \\ 20: 20, 40, 60, 80, 100, 120, 140, 160, \textcircled{180}, 200 \end{array}$$

\hookrightarrow LCM

Again, prime factorization is useful!

Ex: Lcm between 18, 20, and 30

$$\begin{array}{c} 18 \\ \backslash \quad \backslash \\ 2 \quad 9 \\ \backslash \quad \backslash \\ 3 \quad 3 \end{array}$$

$$\begin{array}{c} 20 \\ \backslash \quad \backslash \\ 5 \quad 4 \\ \backslash \quad \backslash \\ 2 \quad 2 \end{array}$$

$$\begin{array}{c} 30 \\ \backslash \quad \backslash \\ 5 \quad 6 \\ \backslash \quad \backslash \\ 2 \quad 3 \end{array}$$

* Look at each factor and select the one with the largest exponent *

$$18 = 2 \times 3^2$$

$$\begin{aligned} 20 &= 2^2 \times 5 \\ 30 &= 2 \times 3^2 \times 5 \end{aligned}$$

exponents are equal, doesn't matter which you select.

$$\Rightarrow 2^2 \times 3^2 \times 5 = 180$$

∴ The LCM is 180
